Osmosome: new targets in the treatment of sickle cell anemia. Sickle cell anemia (SCA) is a major health issue in African populations. While recent progress have allowed for a better understanding of the molecular pathogenesis of the disease, which include the role of cytotoxic free radicals and the intracellular pH, no effective treatment has been identified to date. Furthermore, available methods for the delivery of drugs to the cells are limited. Vesicles, naturally occurring and artificially created, are capable of carrying molecules inside or outside their membrane depending upon the nature of their matrix and composition. An interesting group of nanoparticles, "osmotically active vesicles" (osmosomes), are sensitive to the microenvironment of their surroundings and their volume can change from large to small vesicles. Therefore, these vesicles are capable of transporting molecules inside or outside their membranes, which can be useful for developing drug delivery systems. In addition, SCA patients express abnormal cell-surface proteins that can be target for drug delivery. Utilization of osmotic vesicles will allow to modulate the pathophysiological properties of abnormal surface proteins. The aim of this review is to discuss the scientific basis of the osmotic vesicles and highlight the potential of these vesicles to deliver drug to SCA cells to alter the pathophysiology of these cells.
